(54) Title: CRYOGENIC MAPPING AND ABLATION CATHETER

(57) Abstract

The invention provides a catheter (10, 100) for ice mapping and ablation and a method of using the catheter. The catheter includes two conduits (16, 14) for circulating a refrigeration fluid adjacent an ablation device (12, 22, 110, 144) located at the end of a catheter. The refrigerated ablation device is used to chill a localized region of tissue. The ablation device may be used to make a lesion in the myocardial tissue to correct a cardiac arrhythmia. In one embodiment, the ablation device is an electrode which uses radio frequency energy to ablate tissue. Alternatively, the ablation device is an electrode adapted for direct current ablation. In another embodiment, the electrode is replaced with an optical fiber (40) which uses the laser light energy to ablate tissue. Yet another embodiment is a cryogenic catheter having combined or separate mapping and ablation devices. In another embodiment, a cryogenic catheter (130) is provided having an inner conduit (140). The embodiments may include provisions for steering the catheter and for stabilizing the ablation device at the proposed lesion site.

CRYOGENIC MAPPING AND ABLATION CATHETERCROSS-REFERENCE TO RELATED APPLICATIONS

10

This instant invention is a continuation-in-part of co-pending and commonly-assigned U.S. Patent Application Serial No. 07/898,142, filed June 15, 1992 (our File MSPI-003XX), which is a continuation-in-part U.S. Patent Application Serial No. 07/870,495, filed April 16, 1992 (our File No. MSPI-002XX).

FIELD OF THE INVENTION

15

The invention relates to the field of catheters, and more particularly to a catheter used in cardiac procedures.

BACKGROUND OF THE INVENTION

20

Cardiac arrhythmias are caused by localized electrophysiologic phenomena. These are of generally two types: additional foci or reentrant circuits. Reentrant circuits can be highly localized, as in ventricular tachycardia postinfarction or AV node reentry, or can be of a grosser morphology, as in accessory pathway pathologies. Since they are localized phenomena, they can be treated surgically. The task is to remove or destroy the offending region, thereby eliminating the source of the arrhythmia.

25

30

35

Current surgical therapies include: cardiotomy; open chest cryoablation; closed-chest catheter radio frequency (rf) ablation; and closed-chest direct current ablation. Radio frequency catheter ablation is becoming the therapy of choice. The greatest drawback of rf ablation is that, prior to ablation, the site of the intended cardiac lesion must be determined by conventional electrocardiographic mapping. Unfortunately, conventional mapping does not provide definitive isolation of the problem area. In a great majority of cases, more than one lesion must be made in order to effect a cure. Multiple lesions are required because the effectiveness of each of the proposed lesion sites cannot be

- 2 -

predetermined due to the limitations of conventional electrocardiographic mapping. Often five lesions, and sometimes as many as twenty lesions may be required before a successful result is obtained. Usually only one of the lesions is actually effective; the other lesions result in unnecessarily destroyed cardiac tissue.

Treatment of cardiac arrhythmias through selective ablation of cardiac tissue may be improved if, prior to ablation, the local electrical activity of the region can be suppressed to determine the effectiveness of the proposed lesion site in stopping the arrhythmia. Localized electrical activity may be suppressed by chilling small regions of myocardial tissue and then performing electrocardiographic mapping to evaluate the arrhythmia. This technique of cooling and mapping is called "zero-degree" or "ice" mapping. If the proposed lesion site would be effective, as determined by the ice mapping, to eliminate the arrhythmia, the site is ablated. Despite the advantages of cryoablation, it has not been the technique of choice for want of a single, easily operated device which effectively combines the functions of cryogenic cooling of cardiac tissue and tissue ablation.

SUMMARY OF THE INVENTION

The invention provides an ablation catheter which combines zero-degree or ice mapping and tissue ablation means in a single device. The invention includes a first and a second conduit for circulating a cooling fluid to the distal end of a catheter which includes an ablation device. The ablation device may be one pole of a multipole mapping electrode which conducts radio frequency energy, or direct current energy for tissue ablation. Alternatively, the ablation electrode may be replaced with an optical fiber in communication with a laser. The light energy is dispersed by a light diffuser toward a lesion site to ablate the tissue. The catheter may have an optional steering device to curve the distal end of the catheter, and the ablation

- 3 -

device may be held in contact with the myocardial tissue with the aid of a pointed ridge.

Another feature of the invention is a method for ice mapping and ablation using the above-described catheter. The catheter is inserted through an artery or vein into the heart or into a cardiac vessel and placed against the site of a proposed lesion. Cooling fluid is circulated to the tip of the catheter through the conduits, thereby cooling a localized region of cardiac tissue. The electrical activity of the heart is then measured to evaluate the effectiveness of the proposed site. If the test results indicate that a lesion would eliminate a cardiac arrhythmia, the region is ablated with either radio frequency, direct current or laser light energy.

Yet another embodiment of the invention is a cryogenic device useful for cardiac cryosurgery, mapping, any endoscopic cryosurgery or as a cryoprobe in open surgical procedures. The invention provides a first conduit within a second conduit for circulating a pressurized refrigerant at a cooling tip. Flow control of the fluid is achieved through either a passive ball and spring device or an active, electric control valve.

In still another embodiment of the invention, a cryogenic catheter has concentrically disposed conduits, wherein an inner lumen has a reduced inner diameter near a distal end leading to a boiling chamber. A passive flow restriction device controls flow of boiled off gas from the boiling chamber into an outer gas return conduit. The gas return line can be held at a reduced pressure to prevent escape of gas from the catheter.

BRIEF DESCRIPTION OF THE DRAWINGS

A more complete understanding of the present invention and attendant advantages and features thereof will be more readily understood by reference to the following detailed

DETAILED DESCRIPTION OF THE INVENTION

Fig. 1 is a schematic of an embodiment of the ice mapping and ablation catheter 10. The catheter 10 has a tip 12 at its distal end which is alternately used for ice-mapping and radio frequency ablation. The proximal end of the catheter 10 is accessible to a surgeon and is connectable to a refrigerant source (not shown). The ice mapping and ablation catheter 10 combines two conduits 14 and 16 within the catheter body 18 to carry a refrigerant to and away from, respectively, the tip 12. The exemplary embodiment of the ice mapping and ablation catheter 10, depicted in Fig. 1, has the following wall dimensions for conduits 14 and 16: outer conduit 16, 0.117" Outer Diameter (O.D.) by 0.088" Inner Diameter (I.D.); and inner conduit 14, 0.068" O.D. by 0.060" I.D.

In the embodiment shown, the tip 12 includes a first electrode 20, circumferentially disposed on the catheter body 18, and a second electrode 22, both connected to an electrical signal amplifier with wires 23. The first and second electrodes 20 and 22 are used together to perform electrocardiographic mapping. The electrodes 20, 22 are made

- 6 -

of an electrically conductive material such as copper, silver or aluminum, which is plated with gold, platinum or titanium. The second electrode 22 also acts as a thermal conductor between the catheter tip 12 and cardiac tissue when a refrigerant is passed through the inner conduit 14 to the tip 12. For radio frequency (rf) ablation, a wire 23 supplies (rf) current to the second electrode 22 which acts as an ablation device.

In other embodiments, additional electrodes may be added to the tip 12 to make a multipole mapping electrode. In another embodiment, a conductive refrigerant may be used to provide the electrical connection to the first electrode 20, thereby obviating the need for wires 23. In yet another embodiment, the refrigerant is an electrically insulating fluid like trimethylsiloxyl terminated polydimethylsiloxane, and the wires 23, free of insulation, may be located within the conduits 14 and 16; one wire 23 in the inner conduit 14, and one wire 23 in the outer conduit 16. The combination of the insulating fluid and the insulating effect of the walls of the lumens 14 and 16 electrically isolate the wires 23 from each other.

In all of the embodiments, the ablation surface or device on the tip 12 is not necessarily the second electrode 22. The ablation device may be a separate surface which is distinguishable from the second electrode 22. In some embodiments, it may be desirable to entirely omit the first and second mapping electrodes 20 and 22 from the catheter 10, and to perform electrocardiographic mapping by other means, such as non-invasive cardiac monitoring.

When the catheter 10 is used for ablation, the second electrode 22 and a third electrode 24, shown in Fig. 2, are employed. Fig. 2 is a representative cross-section of a human chest cavity 26 depicting approximate locations of a heart 28, lungs 30 and spinal column 32. The patient is shown resting on a conductive plate or third electrode 24. The ice-mapping and ablation catheter 10, which is smooth

- 7 -

enough to pass easily through blood vessels and heart valves, is shown inside the heart 28. Creation of an electrical potential difference between the second electrode 22 and the third electrode 24 permits controlled ablation of cardiac tissue. The third electrode 24 may also be used for electrocardiographic mapping. In another embodiment of the catheter 10, shown in Fig. 3, a reconfigured tip 12 houses an elongated second electrode 22 useful for direct current ablation.

The catheter 10 of Fig. 1 is better understood with reference to its use in an operative procedure. Following the determination of a proposed lesion site by electrocardiographic mapping, using the first and second electrodes 20 and 22 with a method known in the art, the ice mapping and ablation catheter 10 is directed to the proposed region where lesions will be made. Following positioning of the tip 12 on the cardiac tissue, the refrigerant flow is turned on to allow a cooling fluid, such as ethyl alcohol, freon, or polydimethylsiloxane to flow from the reservoir within the inner conduit 14 to the tip 12, and then to return to the reservoir via the outer conduit 16. While the flow direction may be reversed, causing refrigerant to be introduced via the outer conduit 16 and withdrawn from the inner conduit 14, the resultant cooling of the exterior of the catheter body 18 would unnecessarily cool blood vessels and require that the refrigerant be colder when introduced into the catheter 10, to allow for warming of the coolant before it reaches the tip 12. In another embodiment of the catheter 10, the catheter body 18 may enclose a "bundle" of conduits as an alternative to the "tube-within-a-tube" configuration depicted in Fig. 1. In all of the configurations, circulation of refrigerant at the tip 12 permits controllable cooling of the tip 12 to cool the proposed lesion site.

An alternative means of cooling the tip 12 is through gas expansion cooling by the Joule-Thomson effect, as is

- 8 -

known in the art in cryoablation. A tip 12 configured for expansion cooling is shown in Fig. 4. The tip 12 has numerous small channels 34 which allow passage of a pressurized gas, such as nitrous oxide or carbon dioxide, from the outer conduit 16 into a gas expansion chamber 36. As the gas expands rapidly, it chills the thermally conductive electrode 22. The cold gas is then withdrawn from the tip 12 through the inner conduit 14. In lieu of pressurized gas, a liquid such as chlorodifluoromethane may be used for cooling. Liquids such as chlorodifluoromethane boil at a low temperature and cool by removing heat of vaporization through boiling.

The exterior wall of the outer conduit 16 is the same surface as the exterior of the catheter body 18 and may include an internal metal braid to make the ice mapping and ablation catheter 10 torqueable for intracardiac manipulation. To further facilitate intracardiac manipulation, a cord, wire or cable 26 may be incorporated with, or inserted into, another conduit so as to make the ice mapping and ablation catheter 10 steerable. In the embodiment of Fig. 5, the cable 26 is attached to the inner conduit 14 at an attachment point 27 near the distal end of the inner conduit 14. When the surgeon tightens or pulls on the cable 26 the distal end of the inner conduit 14 moves within the outer conduit 16. As the distal end of the inner conduit 14 curves, it presses against the distal end of the outer conduit 16 and thereby causes the distal end of the catheter 10 to bend in proportion to the force applied to the cable 26. Conversely when the cable 26 is released, the curvature of the distal end of the catheter 10 is decreased.

It is further contemplated that a piezo-electric plastic, such as polyvinylidene fluoride (trade name Kynar®), be added to the inner or outer surface of the distal end of either the inner conduit 14 or the outer conduit 16 to make the ice mapping and ablation catheter 10 similarly steerable. Referring to Fig. 6, a catheter 10 is shown with an

- 9 -

approximately three centimeter Kynar® segment 38 incorporated into a portion of the wall of the outer conduit 16 near the distal end of the catheter 10. The segment 38 has positive and negative electrical leads connected to an electrical power supply with wires 39. Application of an electric current of one polarity causes the segment 38 contract, which then causes the distal end of the outer conduit 16 to curve. Reversing the electrical polarity causes the segment 38 to expand, thereby causing the distal end of the outer conduit 16 to curve in the opposite direction. The movement of the outer conduit 16 causes a corresponding movement of the inner conduit 14 and permits controlled placement of the tip 12 against cardiac tissue.

It is further contemplated that a second segment 38 be incorporated into a wall portion of the outer conduit 16 opposite the first segment 38. Control of the distal end of the catheter 10 is achieved as with the single segment 38, except that voltages of opposite polarity are applied to the segments 38 simultaneously, thereby causing one segment 38 to contract and the other segment 38 to expand.

An ice mapping and ablation catheter 10, having the exemplary above-referenced wall dimensions and a length of 100 centimeters, requires refrigerant pressurization of approximately 200 pounds per square inch to produce a refrigerant flow of approximately 350 cc/min through the catheter 10. With a refrigerant inlet temperature of -60 degrees Celsius, a 350 cc/min flow, and a polyurethane wall material, the temperature of the tip 12 is approximately -10 degrees Celsius when the catheter body 18 is positioned inside a human body having a nominal temperature of 37 degrees Celsius. This temperature is sufficiently cold to do ice mapping.

The first step in the ice mapping procedure is placing the cooled tip 12 at the proposed lesion site. Because the operative procedure has several steps, the tip 12 must be stabilized at the proposed lesion site for the time necessary

- 10 -

to ice map, to evaluate, and to ablate. A variety of configurations of the tip 12 may be employed to help secure or stabilize the catheter 10 in place against the myocardium. Fig. 7 depicts a pointed tip 12 or second electrode 22; Fig. 8 illustrates a concave tip 12 or second electrode 22 having lip or ridge 41; and Fig. 9 depicts a bulbous tip 12 having a series of ridges 41 on the side of the tip 12. Fig. 10 is a cross-sectional view of the tip 12 of Fig. 9, which more clearly illustrates the configuration of the stabilizing ridges 41.

When the cardiac tissue reaches approximately +5 degrees Celsius, its electrical activity is suppressed. If the proposed lesion site will be therapeutically effective when ablated, the arrhythmia will no longer be inducible once the electrical activity of the proposed site is suppressed by cooling. Having confirmed the effectiveness of the proposed site, rf ablation is performed using the second electrode 22 and the third electrode 24 in manner known to those skilled in the art.

Fig. 11 illustrates another embodiment of the catheter for ice mapping and ablation 10 which incorporates provisions for laser ablation. In this embodiment an optical fiber 40 is passed through the inner conduit 14 to a light diffuser 42 at the distal end of the catheter 10 in the center of the second electrode 22. The optical fiber 40 transmits light energy from a laser positioned at the proximal end of the optical fiber 40 at the proximal end of the catheter body 18. Because the laser light is highly collimated, the light diffuser 42 is used to enlarge the area ablated by the laser energy. Alternatively, the laser light may be used to heat the second electrode 22, as shown in Fig. 12, or a separate thermally conductive element, to a temperature of approximately +80 degrees Celsius for the procedure known as heat ablation. The ice-mapping and laser light or heat ablation procedure is similar to that for radio frequency or direct current ablation, the sole difference being the method

- 11 -

of heat generation. As with rf ablation, the second electrode 22 may incorporate stabilization features as depicted in Figs. 7-10.

5 The embodiment of Fig. 11 is shown configured with optional first and second electrodes 20 and 22 for electrocardiographic mapping, while the embodiment of Fig. 12 is not, to show the possible variety of configurations for the catheter 10. However, it is also contemplated that the catheter 10 of Fig. 12 be configured with mapping electrodes 20 and 22, and that the catheter 10 of Fig. 11 omit them.

10 Figures 13 and 14 depict two cryogenic catheter embodiments which use cooling for both mapping and ablation. Fig. 13 depicts a cryogenic catheter 100 which uses ball and spring valves 102 to control the pressure of a circulating cooling fluid. The cryogenic catheter 100 is constructed in a manner similar to the catheter for ice mapping and ablation 10 of Fig. 1, and has a first or inner conduit 104 positioned within a second or outer conduit 106. In the exemplary embodiment, a liquid under pressure, such as a chlorinated fluorocarbon at 150 pounds per square inch (psi), is pumped into the outer conduit, thence through ball and spring valves 102 to a boiling chamber 108 proximate a metal cooling tip 110, whereby boiling of the cryogenic fluid cools the tip 110. A micropore filter 112 fills the distal end of the inner conduit 104 to prevent any traces of liquid coolant from entering the inner conduit 104 that serves as the gas return line. By this means boiling is confined to the boiling chamber and the cryogenic liquid does not interfere with the return gas pumping.

15 20 25 30 35 The ball and spring valves 102 are arranged about the periphery of the inner conduit 104, and each valve 102 incorporates a helical metal spring or silicone rubber pad serving as a spring 114, pre-loaded to equal or exceed the pressure of the fluid in the outer conduit 106 (e.g., a fluid pressure of 150 psi, and a spring load of 180 psi). The valve 102 may comprise any combination of materials which

- 12 -

produce in a liquid tight seal. In a present embodiment, the ball 116 is stainless steel and the seat 118 is polytetrafluorethylene.

5 In order to cool the tip 110, the fluid pressure in the outer conduit 106 is increased until the ball 116 is displaced from its seat 118, thereby allowing pressurized liquid to enter the boiling chamber 108. The lower pressure in the boiling chamber 108 permits the fluid to vaporize (boil), which causes its temperature to drop and thereby cool
10 the tip 110. Lowering the fluid pressure in the outer conduit 106 to a level below the spring load stops fluid flow into the boiling chamber 108. Because different liquids have different boiling points and vapor pressures, the specific choice of liquid determines the temperature to which the tip
15 110 is cooled and the required pre-load of the spring value.

The cooling tip 110 that is placed in contact with body tissue to be cooled, may be fabricated from any metal such as surgical stainless steel to ensure bio-compatibility. However, copper which provides superior thermal conductivity,
20 or aluminum may be used, and may be coated with gold, silver, or titanium to preclude an adverse bio-chemical reaction by the body.

Referring to Fig. 14, an alternative embodiment of the cryogenic catheter 100 is shown, wherein actively controlled electrically powered valves 120 replace the passive ball and spring valves 102 of Fig. 13 for fluid control. One such
25 valve type is an electric solenoid valve, another is a needle valve. When electrically controlled and powered valves 120 are used, the fluid pressure is held constant within the outer conduit 106. Opening and closing of the valves 120 may be in response to a signal from a remote control unit with
30 allows either manual or automatic temperature regulation or with temperature sensors 122 mounted within the cryogenic catheter 100. The temperature sensors 122 may include at least one thermocouple or thermistor, or other devices well
35 known in the art.

- 13 -

Due to the need for maintaining a uniform temperature at the tip 110, as well as keeping it as cold as possible within the constraints of a given cooling and also to prevent the liquid from entirely filling the boiling chamber and preventing boiling, temperature sensors 122 are especially useful for monitoring tip temperature and for balancing the heat load with the liquid boil off. A temperature sensor 122 is located at the tip 110, in the inner conduit 104, and on the supply side of the filter 112.

Another means of controlling the tip temperature may be achieved by controlling the pressure in the boiling chamber through active pumping or exhausting of the gas, or with in-line flow restriction. By actively pumping out or evacuating the gas from the return gas conduit, the pressure in the boiling chamber 108 is lowered. Because boiling points of liquids decrease with lowered pressure, by this means, the cryogenic liquid in the boiling chamber 108 boils at a lower temperature, thereby lowering the tip temperature further. Conversely, use of a controllable flow restriction device 124 in the exhaust conduit, depicted in Fig. 14, may raise the pressure in the boiling chamber, thereby elevating its boiling temperature and raising the tip temperature

As previously discussed with respect to the catheter 10 of Fig. 1, the inner and outer conduits 104 and 106, respectively, may be functionally reversed for ease of manufacture or to warm the return gas conduit so as to keep the catheter flexible. The conduits may also be incorporated in the catheter in a non-concentric or side-by-side geometry.

The cryogenic catheter 100 may be rigid or as flexible as the catheter for ice mapping and ablation depending on the desired application. When the catheter 100 is flexible, it may incorporate the steering features disclosed with respect to Figs. 5 and 6. The catheter 100 may also incorporate the position stabilization devices discussed with respect to Figs. 7, 8, 9 and 10. Furthermore, the cryogenic catheter of Figs. 13 and 14 may incorporate the ice mapping

- 14 -

and ablation means discussed with respect to Figs. 1, 3, 4, 11 and 12.

Fig. 15 is a simplified illustration of yet another embodiment of a highly flexible cryogenic catheter 130 having a sealed end 132 insertable through one or more blood vessels into a heart, and an apertured end 134 securable to fluid control unit 136. The fluid control unit 136 can include one or more pumps for supplying a fluid having a low boiling point, such as Freon, to the cryogenic catheter 130 at a predetermined pressure, volume, and flow rate, as well as one or more pumps for applying suction or a vacuum to cause or assist evacuation of the fluid from the cryogenic catheter. Additionally, the control unit 136 can regulate the flow of a gas from a pressurized gas reservoir 138 into the cryogenic catheter 130.

Fig. 16 is a longitudinal sectional view of the cryogenic catheter 130 of Fig. 15 that illustrates details of the cryogenic catheter proximate the sealed end 132. A first or inner conduit 140 is positioned within a second or outer lumen 142. The inner conduit 140 is preferably made of steel or other strong metal which can be welded, and has a portion 140' proximate the sealed end 132 with inner and outer diameters smaller than those of the remainder of the inner conduit. In one embodiment, the two sections of the inner conduit are welded together. A boiling chamber 144, to which both the inner conduit 140 and the outer conduit 142 are secured, terminates the sealed end of the cryogenic catheter 130.

In the exemplary embodiment of the cryogenic catheter 130, the boiling chamber 144 is provided with a neck 146 having annular ridges 148, about which a portion of the elastomeric wall of the cryogenic catheter is compressed to maintain the boiling chamber 144 in a sealed relationship with the outer conduit 142. Although selection of a neck 146 having an outer diameter greater than the inner diameter of the outer conduit 140 provides a seal around the neck, the

- 15 -

compressive seal is inadequate to retain the boiling chamber 144 in place under normal operating gas pressures. Accordingly, a supplemental sealing or clamping element 150 is provided to tightly squeeze the outer conduit 142 against the neck 146. In the exemplary embodiment of the cryogenic catheter 130, the clamping element 150 includes a conductive wire wrapped one or more times around the outer conduit 142. Alternatively, such clamping element could be a solid, flat, metal ring.

In addition to holding the boiling chamber 144 in place, the wire of the clamping element 150 can act as one ECG electrode. A second ECG electrode includes the boiling chamber 144, at least a portion of which is electrically conductive. Both the clamping element 150 and the boiling chamber 144 are electrically connected by individual wires 152 and 154, respectively, that transmit electrical activity signals from the electrodes to an appropriate monitoring device.

In the exemplary embodiment of the cryogenic catheter 130, steering wires 156 are shown which are secured to the neck of the boiling chamber 144 at solder joints 158. Alternatively, the steering wires 156 can be wrapped around the neck 146 between adjacent annular ridges 148. Ease and accuracy of steering the sealed end 132 of the cryogenic catheter 130 with the steering wires 156 is greatly enhanced by the structure of the inner conduit 140, because the portion 140' of the inner conduit 140 is thinner and more flexible than the remainder of the inner conduit 140.

The boiling chamber 144 is operative to contain a cryogenic liquid while it boils so that cooling is effected only at the tip of the cryogenic catheter 130. This is important because chilling the outer conduit 142 can cause it to freeze to the vasculature. The boiling chamber 144 includes a first opening through which the inner conduit 140 that supplies the liquid is placed in a fluid tight manner. One or more (preferably three or four) gas exit holes 160

- 16 -

provide a passage between the boiling chamber 144 and the passage defined by the exterior of the inner conduit 140 and the interior of the outer conduit 142 through which the gas produced while it is boiling off and cooling the walls, especially the tip, of the boiling chamber. The gas exit holes 160 are a passive flow restriction device, the amount of the flow restriction determined in part by the size and number of holes.

In an exemplary embodiment, the cryogenic catheter is approximately one meter in length. The inner conduit 140 has a wall thickness of 0.10 millimeters that defines a passage having a 0.18 millimeter diameter which narrows to 0.13 millimeters in the reduced diameter portion 140' of approximately 25 centimeters in length, which has a 0.06 millimeter wall thickness. The outer conduit 142 has a wall thickness of 0.38 millimeters and defines a passage 1.27 millimeters in diameter. The boiling chamber 144 is 6.35 millimeters long, 2.67 millimeters wide, and has a wall thickness of 0.20 millimeters. The gas exit holes 160 are 0.25 millimeters in diameter.

Testing has shown that the particular dimensions of the components of the illustrated cryogenic catheter 130 are critical with respect to proper functioning of this embodiment of the cryogenic catheter. For example, the above-recited dimensions are adapted for cooling phase change (boiling off) of a liquid which requires a much lower flow rate than a device that employs Joule Thomson (gas expansion) cooling. Concomitantly, a device that employs Joule Thomson cooling cannot be adapted to the dimensions recited herein.

A benefit provided by the particular passage diameter (0.13 to 0.18 mm) defined by the inner conduit 140, 140' is that a passage of less than approximately 0.10 mm is readily clogged because any water dissolved in the refrigerant freezes, thus plugging the passage. However, if a passage greater than 0.20 mm is provided, the refrigerant flow cannot be reduced when less cooling is desired, because an exemplary

- 17 -

refrigerant such as Freon has a vapor pressure of approximately 125 PSI at room temperature and 140 PSI at body temperature, precluding delivery of liquid Freon pressures lower than the vapor pressure. For an exemplary refrigerant such nitrous oxide, having a vapor pressure in excess of 800 PSI, the problem is worse. For a passage having a diameter larger than 0.20 mm, so much fluid would be delivered to the tip that it would be flooded and liquid would exit the gas exit holes 160 and flow into the gas return conduit. It should be understood that such an upper limit with respect to passage diameter does not apply to a Joule Thomson device, because gas expansion can be done at any pressure.

An operating pressure range between the vapor pressure of a cryogenic liquid and a selected percentage of the material failure limit of common, biocompatible, extruded plastics can be established by selecting the length of the reduced diameter portion 140' so as to provide a passage (defined by the outer surface of the portion 140' and the inner surface of the outer conduit) having a volume that limits the pressure operating range of the device explicitly between the vapor pressure of the cooling fluid as a minimum and approximately 300 PSI as a maximum. By ensuring that the pressure remains below 300 PSI, patient safety is greatly enhanced, and it permits the catheter 130 to be made from common plastics. Present manufacturing techniques for metal tubing do allow this precise balance between flow requirements and effective and safe operating pressures to be maintained without an inner conduit having at least two diameters. If tubing manufacturing were improved, it could be possible to provide the extremely close tolerance in a single tube diameter.

Another safety feature of the device is provided by the application of a vacuum or a suction to the cryogenic catheter 130, so as to cause the pressure within the outer conduit 142 to be lower than a given blood pressure. Low

- 18 -

pressure gas return provides a particular advantage when the returning fluid used for cooling is toxic, such as gaseous Freon. For example, were the catheter 130 to develop a tear, a hole or other imperfection, blood would be sucked into the catheter instead of the toxic gas being expelled therefrom. Thus, the present invention allows cooling fluids to be used despite their toxicity, thereby making available a broader selection of fluids than would otherwise be available to the prudent practitioner. The reduced pressure in the gas return line also provides protection from excessive discharge of an otherwise benign gas or fluid, such as carbon dioxide, a large bolus of which could be fatal to the patient. Furthermore, the application of a vacuum allows the temperature of the cooling tip to be reduced significantly.

A variety of modifications and variations of the present invention are possible in light of the above teachings. It is therefore to be understood that, within the scope of the appended claims, the present invention may be practiced otherwise than as specifically described hereinabove.

- 19 -

CLAIMS

What is claimed is:

1. A cryogenic catheter comprising:

5 a first flexible conduit, having a proximal end and a distal end, concentric with a second flexible conduit, said first flexible conduit permitting a cooling fluid to flow from said proximal end to said distal end, said second flexible conduit, having a proximal end and a distal end, permitting said cooling fluid to flow from said distal end to said proximal end; and

10 a boiling chamber connecting said distal end of said first flexible conduit and said distal end of said second flexible conduit, said boiling chamber permitting boiling of said cooling fluid into a gaseous state;

15 said cryogenic catheter being sufficiently flexible and sufficiently slender to be inserted into and travel through a blood vessel without injuring said blood vessel.

20 2. The cryogenic catheter of claim 1, wherein said first flexible conduit has a flow restrictive section adapted to control delivery of said cooling fluid to said boiling chamber at a pressure greater than a vapor pressure of said cooling fluid at room temperature and less than 300 pounds per square inch.

25 3. The cryogenic catheter of claim 1, wherein said first flexible conduit has a first portion having a first inner diameter and a second portion proximate said distal end having a second inner diameter less than said first inner diameter and said second flexible conduit has a substantially uniform inner diameter from said proximal end to said distal end.

30

- 20 -

4. The cryogenic catheter of claim 3, wherein said first inner diameter is 0.18 millimeters and said second inner diameter is 0.13 millimeters.

5. The cryogenic catheter of claim 4, wherein said cryogenic catheter is approximately one meter long and said second portion is 25 centimeters long.

6. A cryogenic catheter comprising:

a first conduit, having a proximal end and a distal end, concentric with a second conduit, and having a first portion having a first inner diameter and a second portion having a second inner diameter, said second portion being proximate said distal end and said second inner diameter being less than said first inner diameter, said first conduit permitting a cooling fluid to flow from said proximal end to said distal end, said second conduit, having a proximal end and a distal end, permitting said cooling fluid to flow from said distal end to said proximal end; and

a conductive boiling chamber connecting said distal end of said first conduit and said distal end of said second conduit, said boiling chamber permitting boiling of said cooling fluid into a gaseous state; and

a first electrode wire in conductive contact with said boiling chamber and a second electrode wire isolated from said boiling chamber.

7. The cryogenic catheter of claim 6, wherein said second electrode wire presses a portion of said second conduit against a portion of said boiling chamber.

8. The cryogenic catheter of claim 7, wherein said portion of said boiling chamber includes a plurality of annular ridges.

- 21 -

9. The cryogenic catheter of claim 7, further including a steering wire secured to said boiling chamber.

5 10. The cryogenic catheter of claim 9, further including a second steering wire secured to said boiling chamber and separated from said first steering wire by a distance no greater than an inner diameter of said second conduit.

10 11. The cryogenic catheter of claim 2, wherein said boiling chamber defines a first opening in communication with said distal end of said first flexible conduit and includes a passive flow restriction device between said boiling chamber and said distal end of said second flexible conduit.

15 12. The cryogenic catheter of claim 2, further including a fluid control unit for maintaining a gas pressure within said second flexible conduit at a predetermined level below a given blood pressure.

13. The cryogenic catheter of claim 12 further including a supply of cooling fluid having a low boiling point.

20 14. The cryogenic catheter of claim 12, wherein said cooling fluid is toxic in its liquid state.

15. The cryogenic catheter of claim 12, wherein said cooling fluid is toxic in its gaseous state.

16. The cryogenic catheter of claim 13, wherein said cooling fluid includes Freon.

17. The cryogenic catheter of claim 13, wherein said cooling fluid is harmful to a human when released into a patient's cardiovascular system.

- 22 -

18. A cryogenic catheter comprising:

a first conduit, having a proximal end and a distal end, concentric with a second conduit, said first conduit permitting a cooling fluid to flow from said proximal end to said distal end, said second conduit, having a proximal end and a distal end, permitting said cooling fluid to flow from said distal end to said proximal end, said first conduit having a first portion having a first inner diameter and a second portion having a second inner diameter, said second portion being proximate said distal end, and said second inner diameter is less than said first inner diameter;

a boiling chamber connecting said distal end of said first conduit and said distal end of said second conduit, said boiling chamber permitting boiling of said cooling fluid into a gaseous state, said boiling chamber being conductive and further including a first electrode wire in conductive contact with said boiling chamber and a second electrode wire electrically insulated from said boiling chamber, said second electrode wire pressing a portion of said second conduit against a portion of said boiling chamber; and

a steering wire secured to said boiling chamber.

19. The cryogenic catheter of claim 18, wherein said boiling chamber defines a first opening in communication with said distal end of said first conduit and includes a passive flow restriction device between said boiling chamber and said distal end of said second conduit.

20. The cryogenic catheter of claim 19, further including a fluid control unit maintaining a gas pressure within said second conduit at a predetermined level below a given blood pressure.

21. The cryogenic catheter of claim 18, further including a supply of a toxic cooling fluid having a low boiling point.

- 23 -

22. A method of cooling cardiac tissue comprising the steps of:

providing a cryogenic catheter including,

a first flexible conduit, having a proximal end and a distal end, concentric with a second flexible conduit, said first flexible conduit permitting a cooling fluid to flow from said proximal end to said distal end, said second flexible conduit, having a proximal end and a distal end, permitting said cooling fluid to flow from said distal end to said proximal end; and

a boiling chamber connecting said distal end of said first flexible conduit and said distal end of said second flexible conduit, said boiling chamber permitting boiling of said cooling fluid into a gaseous state;

pumping a toxic cooling fluid into said boiling chamber at a temperature between room temperature and body temperature; and

maintaining a gas pressure within said second flexible conduit at a predetermined level below a given blood pressure.

23. A cryogenic catheter comprising:

a first conduit, having a proximal end and a distal end, concentric with a second conduit, said first conduit permitting a cooling fluid to flow from said proximal end to said distal end, said second conduit, having a proximal end and a distal end, permitting said cooling fluid to flow from said distal end to said proximal end;

a conductive boiling chamber connecting said distal end of said first conduit and said distal end of said second conduit, said boiling chamber permitting boiling of said cooling fluid into a gaseous state;

said first conduit having a flow restrictive section adapted to control delivery of said cooling fluid to said boiling chamber at a pressure greater than a vapor pressure

- 24 -

of said cooling fluid at room temperature and less than 300 pounds per square inch; and

a first electrode wire in conductive contact with said boiling chamber.

24. The cryogenic catheter of claim 23, further including a second electrode wire isolated from said boiling chamber.

25. The cryogenic catheter of claim 24, wherein said second electrode wire presses a portion of said second conduit against a portion of said boiling chamber.

26. The cryogenic catheter of claim 25, wherein said portion of said boiling chamber includes a plurality of annular ridges.

27. The cryogenic catheter of claim 23, further including a steering wire secured to said boiling chamber.

28. The cryogenic catheter of claim 27, further including a second steering wire secured to said boiling chamber and separated from said first steering wire by a distance no greater than an inner diameter of said second conduit.

AMENDED CLAIMS

[received by the International Bureau on 01 June 1995 (01.06.95);
new claims 29-44 added; remaining claims unchanged 4 (pages)]

29. A cryogenic catheter comprising:

5 a first conduit, having a proximal end and a distal end,
concentric with a second conduit, and having a first portion
having a first inner diameter and a second portion having a
second inner diameter, said second portion being proximate
said distal end and said second inner diameter being less
than said first inner diameter, said first conduit permitting
a cooling fluid to flow from said proximal end to said distal
end, said second conduit, having a proximal end and a distal
10 end, permitting said cooling fluid to flow from said distal
end to said proximal end; and

15 a conductive boiling chamber connecting said distal end
of said first conduit and said distal end of said second
conduit, said boiling chamber permitting boiling of said
cooling fluid into a gaseous state; and

a first electrode wire in conductive contact with said
boiling chamber and a second electrode wire isolated from
said boiling chamber.

20 30. The cryogenic catheter of claim 29, wherein said second
electrode wire presses a portion of said second conduit
against a portion of said boiling chamber.

31. The cryogenic catheter of claim 30, wherein said portion
of said boiling chamber includes a plurality of annular
ridges.

25 32. The cryogenic catheter of claim 29, further including
a steering wire secured to said boiling chamber.

30 33. The cryogenic catheter of claim 32, further including
a second steering wire secured to said boiling chamber and
separated from said first steering wire by a distance no
greater than an inner diameter of said second conduit.

- 26 -

34. A cryogenic catheter comprising:

5 a first conduit, having a proximal end and a distal end, concentric with a second conduit, said first conduit permitting a cooling fluid to flow from said proximal end to said distal end, said second conduit, having a proximal end and a distal end, permitting said cooling fluid to flow from said distal end to said proximal end, said first conduit having a first portion having a first inner diameter and a second portion having a second inner diameter, said second portion being proximate said distal end, and said second inner diameter is less than said first inner diameter;

10 a boiling chamber connecting said distal end of said first and said distal end of said second conduit, said boiling chamber permitting boiling of said cooling fluid into a gaseous state, said boiling chamber being conductive and further including a first electrode wire in conductive contact with said boiling chamber and a second electrode wire electrically insulated from said boiling chamber, said second electrode wire pressing a portion of said second conduit against a portion of said boiling chamber; and

20 a steering wire secured to said boiling chamber.

35. The cryogenic catheter of claim 34, wherein said boiling chamber defines a first opening in communication with said distal end of said first conduit and includes a passive flow restriction device between said boiling chamber and said distal end of said second conduit.

36. The cryogenic catheter of claim 35, further including a fluid control unit maintaining a gas pressure within said second conduit at a predetermined level below a given blood pressure.

37. The cryogenic catheter of claim 34, further including a supply of a toxic cooling fluid having a low boiling point.

- 27 -

38. A cryogenic catheter comprising:

5 a first conduit, having a proximal end and a distal end, concentric with a second conduit, said first conduit permitting a cooling fluid to flow from said proximal end to said distal end, said second conduit, having a proximal end and a distal end, permitting said cooling fluid to flow from said distal end to said proximal end;

10 a conductive boiling chamber connecting said distal end of said first conduit and said distal end of said second conduit, said boiling chamber permitting boiling of said cooling fluid into a gaseous state;

15 said first conduit having a flow restrictive section adapted to control delivery of said cooling fluid to said boiling chamber at a pressure greater than a vapor pressure of said cooling fluid at room temperature and less than 300 pounds per square inch;

a first electrode wire in conductive contact with said boiling chamber; and

20 second electrode wire isolated from said boiling chamber.

39. The cryogenic catheter of claim 38, wherein said second electrode wire presses a portion of said second conduit against a portion of said boiling chamber.

40. The cryogenic catheter of claim 39, wherein said portion of said boiling chamber includes a plurality of annular ridges.

41. The cryogenic catheter of claim 38, further including a steering wire secured to said boiling chamber.

- 28 -

42. The cryogenic catheter of claim 41, further including a second steering wire secured to said boiling chamber and separated from said first steering wire by a distance no greater than an inner diameter of said second conduit.

43. The cryogenic catheter of claim 38, wherein said first flexible conduit has a first portion having a first inner diameter and a second portion proximate said distal end having a second inner diameter less than said first inner diameter and said second flexible conduit has a substantially uniform inner diameter from said proximal end to said distal end.

44. The cryogenic catheter of claim 43, wherein said first inner diameter is 0.18 millimeters and said second inner diameter is 0.13 millimeters.
